What To Do about Buffalo Gnats or Black Flies

What are they?
Black flies are tiny blood-sucking flies in the insect family Simuliidae and are often called buffalo gnats. Contrary to their name, black flies may be gray, tan, or even greenish. They usually breed in fast moving water of streams and rivers and are tremendous pests of humans, domestic animals, and wildlife every spring in northern areas of the United States and Canada.

In Mississippi, buffalo gnats are usually not a problem, but every so many years outbreaks are reported. The last couple of years there have been numerous reports of buffalo gnats attacking chickens in Wilkinson, Amite, Issaquena, and Warren counties. Mississippi has at least two pest buffalo gnat species – the southern buffalo gnat, *Cnephia pecuarum*, and the turkey gnat, *Simulium meridionale*.

What harm can they do?
Buffalo gnats can kill chickens and livestock by nuisance effects alone. There have been reports of deaths of birds and livestock because heavy swarms attack them, causing them to stampede, trampling younger animals, and sending them crashing into structures. And suffocation has been blamed for some deaths in chickens after buffalo gnats clogged the respiratory tracts.

Sometimes wild birds and poultry have died from a toxic shock-like syndrome caused by the saliva from black fly feeding. In addition to the nuisance effects, certain species of buffalo gnats may transmit various diseases, including leucocytozoonosis, a disease of turkeys, geese, ducks, and sometimes chickens.

What can be done?
Fortunately, buffalo gnats are daytime biters and rarely venture indoors. So, one thing you can do is go inside if the gnats are biting. Providing shelters for poultry may help, since the flies don’t like enclosures. Secondly, you can provide screen-wire enclosures for your birds that block black fly biting. Although not specifically labeled for black flies, on-animal products are labeled for mosquito and biting fly control that you can apply directly to chickens.

Many of these products contain the active ingredient permethrin. One example is Permethrin II® spray insecticide. Another product, called Ravap®, has different active ingredients (tetrachlorvinphos and dichlorvos) and may also be used directly on poultry.
Remember to read and follow all label directions for exact amounts and dilutions for these and any other insecticides, especially when using on-animal products.

Repellents containing DEET have been reported effective for humans (but may need to be reapplied frequently), and wearing light-colored clothing may help keep the gnats away. People being tormented by buffalo gnats should be encouraged by the fact that the adult flies generally only live 4 to 5 weeks and should go away in hot summer.

**Whom can I call if I have questions?**

Questions about black flies in general can be directed to Dr. Jerome Goddard, Extension medical and veterinaryentomologist at Mississippi State University, 662-325-2085. Questions about possible disease transmission can be directed to the Mississippi Board of Animal Health (animals) or the Mississippi Department of Health (humans).
